Abstract (en)
[origin: EP1378578A1] A free-cutting Ni-base heat-resistant alloy excellent in the high-temperature strength and corrosion resistance was proposed. The alloy contains Ni as a major component, 0.01 to 0.3 wt% of C and 14 to 35 wt% of Cr, and further contains at least one element selected from Ti, Zr and Hf in a total amount of 0.1 to 6 wt%, and S in an amount of 0.015 to 0.5 wt%. The alloy has dispersed in the matrix thereof a machinability improving compound phase, where such phase contains any one of Ti, Zr and Hf as a major constituent of the metal elements, essentially contains C and either S or Se as a binding component for such metal elements. The alloy also satisfies the relations of $WTi + 0.53WZr + 0.27WHf > 2WC + 0.75WS$ and $WC > 0.37WS$, where WTi represents Ti content (wt%), WZr represents Zr content (wt%), WHf represents Hf content (wt%), WC represents C content (wt%) and WS represents S content (wt%). This successfully suppresses the amount of free S residing in the alloy, which results in an improved machinability while preventing the hot workability from being degraded.
