Abstract (en)

[origin: WO02083538A1] The invention relates to a method and to winding machinery, which are used to maintain an essentially constant traversing width (Hp) of the thread during the course of the winding path, despite the action caused by changes to a winding angle (  $\alpha$  ), in particular the skip action of said winding angle, as a result of predetermined measures, allowing the front faces of the bobbin to essentially form one plane. The adaptation of the traversing stroke or of the given distance is used in particular during a stepped precision winding to prevent a saw-tooth structure, which can form on the front faces of the bobbin without the inventive measures, as a result of the changing winding angle or the changing speed of the traversing stroke.
