Abstract (en)  
[origin: WO03065303A1] Systems for wireless identification, similar to the barcode-system, wherein mobile data carriers known as transponders, are placed on objects to be identified, whereby the data thereof can be read out and optionally modified by (writing) and reading devices, are already known per se. A transponder contains only a small amount of information, whereby the duration of the reading process is minimal. However, it is not possible to transport large amounts of information. Also, on the other hand, the desire to read as many transponders successively as quickly as possible corresponds to a need in the use of transponders in products when production processes or the like require a high throughput in the shortest amount of time possible.
