Abstract (en)  
[origin: WO2004006088A2] The invention concerns a method for differentiating between data and instructions thereby providing against certain attacks in a data processing device such as a smart card, whereby a generator (30) associates a random number with an applicative component of a downloaded application (AP), and a transformer (42) comprised in a virtual machine (VM) applies each of the instruction words (OC1) in the component and the associated random number to a transformation function (FT) so as to store the transformed instruction words (OCT1) when downloading the component. A second transformer (43) applies each of the transformed words (OCT) of part of the component (CP1) and the associated random number (NA1) to the reciprocal function (FT<-1>) of the transformation function (FT) so as to retrieve the instruction words constituting said component part to execute same.
