Abstract (en)

[origin: EP1560164A1] The method involves detecting presence of a mail article with respect to a given point of reference surface, at distances (d1, d2) near and away from the surface. The distance (d2) corresponds to dimensional threshold. Ratio of presence durations (t1, t2) of the article is compared with a value, by a comparing module (33). Height of the article is considered greater than the threshold if the ratio is greater than the value. The value is equal to $1-\epsilon$, where epsilon represents a corrector coefficient lower than 1 depending on detection tolerances of presence of the article. An independent claim is also included for a system of determining mails postage amount, including a mail article height verifying device.
