Abstract (en)  
The voltage controlled oscillator comprising a ring oscillator outputs an oscillating signal of which the duty cycle is almost 50% in spite of the high frequency. Each of the delay inverting circuits (10,20,30) in the ring oscillator varies the output signal from the "L" level to the "H" level for the constant delay time  $t_r$  when the input signal varies the "H" level to the "L" level. It also varies the output signal from the "H" level to the "L" level for the variable delay time  $t_f$  in response to the delay control voltage  $V_c$  when the input signal varies the "L" level to the "H" level. The output signal from the ring oscillator comprising the delay inverting circuits (10,20,30) is applied to another delay inverting circuit (40). The another delay inverting circuit responses at the constant delay time  $t_r$  when the input signal varies the "H" level to the "L" level, and responses at the delay time  $t_f/2$  in accordance with the delay control voltage  $V_c$  when the input signal varies the "L" level to the "H" level. As a result, the another delay inverting circuit outputs an oscillating signal of which the duty cycle is almost 50%.
