Abstract (en)
[origin: WO2004070127A1] The brick system with horizontal and vertical connective king-slots for complete building construction and decoration consists of parallelepiped, corner, T- or crossshaped bricks, curved and formed, which through horizontal and vertical female recesses and male prominences and with the help of king-rails at their base or optional on the sides and on the roof of the building, they are connected unbreakably together for the creation of an aseismic masonry construction and for the support of the building levels and the roof. The advantages of this invention are many in relation to already existing building systems, because: It offers new building possibilities, for easy and quick construction. It offers a uniform and absolute construction coherence, which makes the building aseismic. Due to the perfect connection of the bricks with bonding materials, the contractor is saved from plaster since they are replaced by stucco. The construction work is clean. The time required to complete the work is very little. It contributes to the economy of the labour and the material and as a result the total cost of the construction is much smaller.
