Abstract (en)

[origin: FR2854790A1] The procedure consists of fixing a transfer component (2) to each of the implants (1) previously fitted in the patient's mouth and taking an impression, e.g. with a self-hardening material, of the transfer components to form a block (A) giving the precise alignment of the implants for drilling the prosthetic tooth support bar. The impressions are taken with the aid of a plate (3) with holes (4) of greater diameter than the transfer components, resting on supple rings (8), e.g. of rubber, placed over the transfer components adjacent to the gum (6). The top of the plate avoids any spillage of the impression material, which can be plaster or a self-polymerising resin.
