Abstract (en)
[origin: WO2004107991A1] The invention relates to a bone clamp (1) which is made of the following elements, A) two branches (2,3) and each branch comprises a free end (4,5) and a rear end (6,7). Both of the rear ends (6,7) are connected to each other by means of an elastically deformable bridge (8) and both branches (2,3) define a plane (9). B) Both branches (2,3) in the non-deformed state of the bridge (8) converge in such a manner that both free ends (4,5) are closer to each other than both of the rear ends (6,7). The bridge (8) is not straight and can be elastically deformed such that the distance of both rear ends (6,7) of the two branches (2,3) increases. The two branches (2,3) are aligned in an essentially parallel manner in relation to each other, in a separate or simultaneous way such that they can be guided into the bones.
