Abstract (en)

In a method for driving gripper heads in gripper looms by servo-motors (3) directly driving the gripper carrier guiding the heads via cog wheels and supplied with motion control data dependent on successively activatable signals from a control unit, (a) the motors are alternating or multiphase current motors of rated speed 3000 rpm or more and intrinsic inertia less than 0.006 kg.m², (b) starting control data are retrievably stored as standardized transfer functions and motion parameters, (c) the activatable signals are high resolution rotation angle signals for the loom main shaft (11) and (d) the transfer functions and motion parameters for issuing motor control signals are retrieved simultaneously (individually or as stored combinations). An independent claim is included for a drive mechanism for gripper heads in gripper looms, comprising: servo-motors (3) outside the fabric former and having drive wheels (34) mounted on the shafts; gripper carriers (21) for guiding the gripper heads (2) into and out of the fabric former, acted on by the drive wheels of the servo-motors via cog elements; and a control unit and memory for supplying with motion control data to the servo-motors, the angle supplier (121) on the main shaft (11) of the loom and the angle supplier (32) on the axes of the servo-motors. The novel features are that: (1) the servo-motors (3) are alternating or multiphase current motors of rated speed 3000-7000 (preferably 550-6500) rpm and maximum rotational moment 140-200 Nm; (2) the angle suppliers on the main shaft and/or the axes of the servo-motors have more than 50 support sites per revolution; and (3) the intrinsic inertia of the moving parts of each servo-motor is less than 0.006 kg.m².
