Abstract (en)

[origin: WO2005032113A1] The invention relates to a method and to a communication system for the detection of at least one other communication device which can be connected to at least one subscriber connection line. The transmission function (Hcurrent) of the at least one subscriber connection line (TAL) is monitored with respect to significant modifications in order to detect at least one additional communication device (C) which can be connected to at least one subscriber connection line. The detection of at least one other communication device (c) connected to the subscriber connection line is displayed if a significant modification of the transmission function (Hcurrent) is determined. Advantageously, communication devices (C) and/or listening devices having high input impedance connected to the subscriber connection line (TAL) can be detected.
