Abstract (en)  
[origin: WO2005049952A2] The invention relates to a locking system for the opening of a building for protecting the inside thereof and preventing an external medium to penetrate into said opening comprising a cover body which covers at least essentially said opening and extends with a split in the surface area of the building adjacent to the building opening, a sealing element by means of which at least the part of a split arranged between the cover body and the surface area and exposed to the medium action can be sealingly closed against said medium. The aim of said invention is to deliver a cost-effective system ensuring a sealing closure against the medium. For this purpose, the sealing element is sealingly jointed to the cover body and when the locking system is actively mounted on the opening, said sealing element extends in the form of a spacer bar in the direction of the surface area and can be attached thereto by a contacting area and said contacting area can be applied to the space area by a pressure force produced by the locking system.
