Abstract (en)
[origin: WO2005054634A1] A compressor comprises a rotor (13) which has several rotor blades (14, 14') which are arranged successively at a distance from each other in an axial direction. A plurality of heat-accumulating segments (10), which are detachably fixed to the rotor (13) in a successive manner in the direction of the periphery and which can be displaceably mounted in the direction of the periphery, are arranged between adjacent rows of rotor blades (14, 14') on the periphery of the rotor (13). Security means (15) are provided on the heat-accumulating segments (10). Said security means are used to secure the heat-exchanging segments against displacement in the direction of the periphery. Production and mounting of the inventive rotor are simplified by virtue of the fact that only one part of the heat-accumulating segments (10) is provided with said security means (15).
