Abstract (en)

[origin: EP1719687A2] Method involves solving of acceleration phase by differential equation  $v'(t) = av^2(t) + bv(t) + c$ , with speed  $v(t)$  and parameters  $a, b, c$  depending on the time  $t$ , by formulae. These formulae are to be used with constant speed or constant braking deceleration in order to determine travel time for train travel. During positive acceleration  $v'(t)$  greater than 0, it examines, whether the sufficient distance is there to attain maximum permissible speed. During negative acceleration  $v'(t)$  less than 0, it is examined, that whether the train eventually comes to a standstill and the point of time of the standstill and thereby mileage distance is determined. During the steady travel  $v'(t) = 0$ , a break-down speed of  $v_0$  is maintained. Basically a specific limitation is allowed for a exit speed by a timely application of a braking device.
