Abstract (en)

Between the shim (1) which receives the end of the slat and the frame (2) of the bed base, there is an elastically deformable flexing element (3), which includes two rings, one inner one (10) and another larger outer one (11), an adjustment device (15) working with said rings, able to be positioned between the inner ring (10) and the base of the flexing element (3), only the smaller ring (10) becoming operative and achieving the maximum tautness in the transmission of forces towards the frame (2), said adjustment device (15) being situated in a horizontal position, closing the outer or encircling ring (11), which thus becomes operative, whereby a degree of intermediate tautness is achieved, or said adjustment device (15) being removed, whereby the degree of tautness of the transmission is minimal, in other words, acquiring three levels of elasticity or shock absorption in the transmission of forces from the slat to the frame of the bed base.
