Abstract (en)
[origin: US2008045975A1] A motor-driven epilation head for an epilation apparatus. The epilation head includes a rotatable cylinder, which can rotate about an axis of rotation, and several pairs of first clamping elements and second clamping elements that cooperate to take hold of and pluck the hairs. The first clamping elements are individual components that are movably suspended in order to be brought in clamping contact with second clamping elements, and can be individually actuated by means of one respective actuating element. The clamping contact between the first clamping elements and the second clamping elements is disengaged by means of spring elements that act upon the first connecting elements independently of the actuating elements. The axis of rotation of the rotatable cylinder extends outside the first clamping elements.
