Abstract (en)

[origin: WO2006048558A1] The invention relates to a thermochemical device and method for producing very low-temperature refrigeration. The inventive device produces refrigeration whose temperature  $T_f < -20^\circ\text{C}$  from a heat source available at a Th temperature of  $60-80^\circ\text{C}$  and a heat sink at an ambient temperature To of  $10-25^\circ\text{C}$ . Said device comprises two coupled dipoles operating in an opposite-phase mode. Thermochemical phenomena in one dipole are such that said dipole can produce refrigeration at the  $T_f$  by means of a heat sink at the ambient temperature To. The thermochemical phenomena in the other dipole are selected such that said dipole is regeneratable from a heat source Th and the heat sink at the temperature To.
