Abstract (en)

[origin: EP1826308A1] Device for closing and opening the access (2) to a compartment (3), in which said access (2) is formed in a wall (1) of the structure of a machine, comprising a hatch (5) displaceable about a virtual axis of rotation (V-V) between a first position where it is arranged over the access (2) of the said compartment, causing closing thereof, and a second position, angularly displaced with respect to the first position, where the access (2) to the compartment is free, as well as resilient recall means (12) acting on said hatch (5). The hatch (5) is provided with a pair of feet (6, 7) which are integral with the inside wall (5b) and inserted inside respective openings (8, 9) and are slidable inside the latter following the angular displacements, said openings (8,9) acting as guides for the feet (6, 7). The resilient recall means (12) comprise parts (16, 17) each of which is engaged with the free end (10, 11) of a respective foot (6, 7) and presses against the said wall (1) of the machine when the hatch (5) is displaced into its second position where the access (2) to the compartment is free.
