Abstract (en)  
Provided is an elevator control panel which enables a door to be developed (opened) during maintenance work in a minimum space at the front face of the main body of the control panel without being hindered by equipment and the like. There is provided a control panel of a machine-room-less elevator which is installed within a shaft and to whose interior access is made by opening a door from on a car or from within the car during maintenance work. The control panel includes a control-panel main body and a door which is constituted by multiple strip-like door units. The door is rotatably connected to at least one side end portion of the control-panel main body and blocks a front face of the main body so as to be capable of opening and closing the front face. The multiple strip-like door units are connected so as to be capable of being folded in each other and of being developed, thereby enabling the door to be opened in a development space at the front face of the control-panel main body which has a depth dimension equal to a width of one door unit when the door is opened.
