Abstract (en)

[origin: EP1912471A2] The method involves filtering two input signals (901, 902) for producing four intermediate signals with different coefficients. The four intermediate signals are added for producing different output signals (930, 931). The input signals are assigned to a defined signal position, and a correlation of the output signals is determined. One of the coefficients is changed depending on the assigned defined signal position and on the correlation. An independent claim is also included for a device for processing input signals in a hearing aid.
