Abstract (en)

[origin: WO2007069929A1] The invention concerns a three-dimensional intelligent position and motion capacitive sensor, for determining x, y, z coordinates and the trajectory of a characteristic point pertaining to an object located inside the sensor. The technical problem solved by the present invention consists in determining the coordinates and the trajectory of a characteristic point of an object following modification of certain differential capacitances over the three axes, caused by the presence of the object in a certain position inside the sensor. The inventive intelligent sensor consists of a differential capacitive sensor (A) consisting of several fixed armatures (2, 3, 4, 5 and 6) arranged on the surface of a prismatic body, so as to define a first rectangular differential capacitance C_{x} formed by the armatures (2, 4 and 5) between the first armature (2) and the second armature (4) being a right angle, and between the second armature (4) and the third armature (5) being also a right angle, a second rectangular capacitance C_{y} being defined by the armatures (3, 4 and 6) in the same way as the capacitance C_x , a third simple rectangular capacitance C_z being defined by two armatures (3 and 4) likewise arranged at an angle of about 90° . The differential capacitive sensor (A) is connected to a block (B) for converting the values of the capacitances into digital dimensions, the block (B) being in turn connected to a block (C) for computing data which computes the coordinates x, y, and z of the characteristic point P(x,y,z) pertaining to an object introduced in the inner space of the differential capacitive sensor (A) and transmits same to a terminal block (D).
