Abstract (en)

[origin: WO2007071669A1] In a terminal device for controlling access to multicast services (SESG, SDI-SDN) over a broadcasting network (RD), an application (APMM) outputs a user-preselected broadcast service request to a router that receives the broadcast services. The request contains an address of the selected service. The device includes a filtering entity (MF) that compares the address (ADn) in the request with addresses in an address list (LST) generated on the basis of at least one filtering criterion (CF) in order to authorise the transmission of the selected service from the router (RT) to the application (APMM) so that the service is delivered when the address is included in the list.
