Abstract (en)

In general, techniques are described for securely exchanging network access control information. The techniques may be useful in situations where an endpoint device and an access control device perform a tightly-constrained handshake sequence of a network protocol when the endpoint device requests access to a network. The handshake sequence may be constrained in a variety of ways. Due to the constraints of the handshake sequence, the endpoint device and the access control device may be unable to negotiate a set of nonce information during the handshake sequence. For this reason, the access control device uses a previously negotiated set of nonce information and other configuration information associated with the endpoint device as part of a process to determine whether the endpoint device should be allowed to access the protected networks.
