Abstract (en)

[origin: WO2008036992A2] Disclosed are a method and a device for monitoring loudspeaker lines. In said method, a least one alternating current signal having a predefined frequency is fed to a loudspeaker line, the voltage and current are measured, and the input impedance on the line is determined therefrom and is compared with a reference value. In order to determine an impedance that is to be compared with a reference value (Z_{Ref}) in a measurement process, a plurality of analogue measured voltage and current values are converted into digital signals which are subjected to Fourier transformation, a corresponding plurality of impedance values are determined from the Fourier-transformed current and voltage values, said impedance values are averaged, and the obtained mean value is compared with a reference impedance value. An error signal is output if the obtained mean value deviates from the reference impedance value by a defined tolerance value.
