Abstract (en)
[origin: WO2008073025A1] The present invention relates to a solution for controlling a gearshift lever (100) in a motor vehicle, wherein a gearshift lever (100) of a control device is movable between at least two gear positions (A, B, C, D, E, F). An energy emitter means (115) at a distal end (112) of the lever (100) emits a lever signal representative of the location of the lever (100), and a transducer matrix (120) is configured to contactlessly detect the lever signal. In response to this signal, the transducer matrix (120) produces a data signal (d), which depending on the lever's (100) location, may be indicative of the gear positions (A, B, C, D, E, F) as well as at least one intermediate position (210, 220, 230) located on a path (P) between at least one first and at least one second position of the gear positions (A, B, C, D, E, F). A central unit (140) receives the data signal (d), and in response thereto, generates a control signal (S_{gear}) and at least one gearbox parameter (P_{gear}). The control signal (S_{gear}) represents a gear to be engaged in the gearbox, and the at least one gearbox parameter (P_{gear}) is adapted to control at least one characteristic of the gearbox other than the gear to be engaged, e.g. a freewheel-clutch operation, and/or a gear-synchronization in respect of an estimated future gear to be engaged.
