Abstract (en)

[origin: EP2107033A1] The jib (10) has a folding-unfolding mechanism (24) that is composed of a lever (26) with an articulation point (32) located on a jib base (12). An operating clearance is created at the level of an articulation point (33) of the lever such that the mechanism is not solicited in a working aligned position of the jib. The clearance is obtained by an elongated slot (37) provided in the lever, where the slot is passed through an axle (36). A width of the slot corresponds to a diameter of the axle. A connecting rod (27) connects an articulation point (34) of the lever to a jib element (13).
