Abstract (en)
[origin: WO2008098797A2] The semiconductor device structure demonstrates a novel organic device concept, capitalizing on knowledge from both the photovoltaic cell and the field effect transistor. This hybrid "photo gated" detector comprises an inorganic capacitive layer, a molecular sensitizing layer and an organic charge transport layer, capped with in-plane gold electrodes defining an active channel. Under illumination, the sensitizer injects an electron in the capacitive layer, constituted by a wide band gap inorganic oxide of mesoscopic morphology, while the resulting positive charge is transferred to the hole- transporter. The increased hole density results in vastly enhanced film conductivity and charge carrier mobility. Strikingly high light/dark current ratios of up to $10^{6.4}$ at low temperature and $10^{3.4}$ at room temperature are observed corresponding to mobility enhancements of up to 10^3 . This not only presents a new method for estimating mobility in organic materials but also offers a broad range of sensing and memory applications.
