Abstract (en)

[origin: WO2009053144A1] During operation of a rolling mill, a rolling product (2) running through the rolling mill is machined by means of a machining device (6). The machining device (6) is controlled by means of a controller (7), to which a target value ( $x^*$ ) and an actual value ( $x$ ) of the roll product (2) are fed after machining by the machining device (6). The controller (7) determines based on the target value ( $x^*$ ) and the actual value ( $x$ ), in conjunction with controller characteristic ( $R$ ), a controlled variable ( $y$ ) for the machining device (6) and outputs the controlled variable ( $y$ ) to the machining device (6). The machining device (6) machines the roll product (2) according to the output controlled variable ( $y$ ). A detection device (8) receives the actual value ( $x$ ) of the mill product (2) after machining by the machining device (6) and a corresponding actual value ( $x'$ ) of the mill product (2) before machining by the machining device (6). Based on the temporal profiles of the actual values ( $x$ ,  $x'$ ) that are fed, said device dynamically determines the controller characteristic ( $R$ ) such that the variance of the actual value ( $x$ ) of the roll product (2) at least tends to be minimized after machining by the machining device (2). Said device also parameterizes the controller (7) according to the determined control characteristic ( $R$ ) determined by it.
