Abstract (en)

[origin: EP2211011A2] The device has a bearing housing for rotatably receiving a drive shaft. A winding coil is provided for a support band. A stop flange fixes an angle end position (A) and another angle end position for lamellas. A turning mechanism moves the lamellas between the angle end positions and locks the lamellas in an angle intermediate position (D). The device locks the lamellas in the intermediate position during raising a jalousie (3). An actuating mechanism actuating a stop element is freewheelingly formed in a rotation direction of the shaft. An independent claim is also included for a method for pivoting lamellas of a jalousie.
