Abstract (en)

[origin: WO2010022908A2] The invention relates to a method and a device for observing a movement profile of at least one driven element of a weaving machine, preferably of at least one heald shaft (1), comprising the steps: detection of at least one measured value, preferably of a plurality of measured values, wherein at least one actual position of the driven element, preferably of the heald shaft, at a definable measuring moment in a weaving cycle and/or an actual moment of the weaving cycle when a definable measuring position of the driven element, preferably of the heald shaft (1), is reached is detected, and determination of at least one characteristic value of the movement profile by means of the at least one detected measured value, preferably by means of the detected measured values.
