Abstract (en)

[origin: WO2010040570A1] The invention relates to a method and to an arrangement for scalable confocal interferometry for distance measurement, for 3-D detection of an object, for OC tomography with an object imaging interferometer and at least one light source. The interferometer has an optical path difference not equal to zero at each optically detected object element. Thus, the maxima of a sinusoidal frequency wavelet, associated with each detected object element, each have a frequency difference  $\Delta f_{\text{Objekt}}$ . In order to record the object, at least one spectrally integrally detecting, rastered detector is arranged. Preferably, the light source is designed with a frequency comb, and the frequency comb differences  $\Delta f_{\text{Quelle}}$  are changed in a predefined manner over time in a scan during measuring. In the process, the frequency differences  $\Delta f_{\text{Quelle}}$  are made equal to the frequency difference  $\Delta f_{\text{Objekt}}$  or equal to an integer multiple of the frequency differences  $\Delta f_{\text{Objekt}}$  at least once for each object element. However, this can also occur through a scan in the object imaging interferometer. In the scan, a modulation in a signal profile is produced and sequentially detected by means of the rastered detector. The present magnitude of the frequency comb differences  $\Delta f_{\text{Quelle}}$  in said signal profile, for example, at the modulation maximum, is determined and is subsequently used to calculate the associated optical path difference of a detected object element. Distances of object elements or changes in the optical path lengths, for example, for a biological microobject, are determined therefrom in a process by imaging.
