Abstract (en)

[origin: EP2196425A1] The method involves detecting a position change of a user as a signal by a movement sensor (17), a load sensor, wireless sensor. The detected signal is compared with a reference signal. A signal-state change is produced when the detected signal does not coincide and/or coincide with the reference signal. A lift facility (100) is partially brought into a discriminatory operating mode for the produced signal-state change. A data communication between the wireless sensor and a portable communication unit is activated within a determined detection region of a functional element. Independent claims are also included for the following: (1) a computer program product comprising instructions for performing a method for discriminatory usage of a lift facility (2) a computer readable medium comprising instructions for performing a method for discriminatory usage of a lift facility.
