Abstract (en)

[origin: WO2010139402A1] The invention relates to a device for cutting food products comprising product feeding means consisting of several parallel advancing devices which are arranged next to each other. Said devices can be driven together in order to simultaneously convey several products, to which a respective conveyor device is associated, to a cutting plane in which at least one blade is displaced. Said conveyor devices comprise a common drive and comprise respectively a belt drive having a primary shaft which can be driven by the common drive, a secondary shaft and a belt having two strands extending between the primary shaft and the secondary shaft. Each belt drive is associated with an adjusting device which is configured in such a manner that the running length of the belt in both of the strands can be changed whilst maintaining the entire running length, in order to individually modify the number of revolutions per minute of the secondary shaft and also the individual conveying rate of the conveying device.
