Abstract (en)
[origin: EP2493001A1] Disclosed is an electrochemical device comprising: a negative electrode having a negative electrode material layer at least on a surface; a positive electrode having a positive electrode material layer at least on a surface; and a solid electrolyte disposed between the negative electrode and the positive electrode, wherein: (1) the solid electrolyte is a solid polymer electrolyte that contains, as a main component, fine composite particles each comprising a polymer brush layer composed of polymer graft chains obtained by polymerization of a monomer having a polymerizable functional group; the fine composite particles form a substantially three-dimensional ordered array structure; and a continuous ion-conductive network channel is formed in each gap of the fine particles, (2) the negative electrode or the negative electrode material layer and/or the positive electrode or the positive electrode material layer have gaps filled with the fine composite particles, and (3) a contact interface between the solid electrolyte and the electrode material layer or the electrode is a polymer brush layer composed of polymer graft chains (the electrode material layer is at least one layer selected from the group consisting of the negative electrode material layer and the positive electrode active material layer, and the electrode is at least one electrode selected from the group consisting of the negative electrode and the positive electrode).
