Abstract (en)

A system for passively controlling clearance in a turbine engine (100) comprises a static assembly (160) arranged circumferentially about an engine rotor assembly (170) and defining a gap (150) between a tip end (112) of the rotor assembly (170) and an adjacent inner surface (132) of the static assembly (160). The static assembly includes a gap control member (130) that defines the inner surface (132), is exposed to the engine working fluid, and comprises a shape memory material selected and preconditioned to deform in a preselected manner in response to a temperature of the engine working fluid. Alternatively, airfoil blades of the rotor assembly include the gap control member (230). A method for passively controlling clearance in a turbine engine (100) comprises assembling the engine so as to define an initial set of build clearances, operating the engine to observe running clearances, configuring a gap control member (130) comprising a shape memory material and re-assembling the engine with the gap control member (130).
