Abstract (en)

[origin: WO2012085206A1] It is herein described a method of immobilization of enzymes, in particular enzymes that are active at the interface with hydrophobic phases as lipases, on porous solid polymeric supports, in which there is formation of a stable covalent bond between the support and the enzyme and in which a hydrophobic "interface" forms around the solid support that allows the enzyme, dissolved in a minimum aqueous phase, to pass from the closed/inactive conformation (which prevails when the enzyme is in aqueous phase) to the open/activated conformation (which prevails when the enzyme comes into contact with a hydrophobic phase) and to adopt an optimum orientation, turning the opening of the hydrophobic active site towards the hydrophobic organic phase.
