Abstract (en)  
[origin: EP2702977A2] The container has a container wall (2) formed with a collapse or target break line in form of a container wall groove (16) in which an independent and regular folding-up of the container is ensured at a bottom of the groove as a result of a gravitational force-conditional outflow of fluid from the container. The wall groove continuously extends around an entire container body circumference along a main center plane (H), which divides the container body in two identical body halves (12, 14), where the wall groove is provided in form of a collection or indentation part of the wall.
