Abstract (en)

[origin: EP2772916A1] The method involves generating (10) a set of successive time frames (y_k) of a digitalized noisy audio signal (y_n), and applying a Fourier transform (12) to the set of successive time frames so as to produce a signal spectrum (Y_{ki}) for each signal time frame. A variable spectral gain (16) is calculated for each frequency band of each current time frame. A modulatable value is calculated by applying increment/decrement to a parameterized nominal value (G_{min}) of a minimal gain for the current time frame.
