Abstract (en)

[origin: WO2013093291A1] The invention relates to a method of detecting a predetermined frequency band in an audio data signal which has previously been coded according to a succession of data blocks (B1; B2, ..., BZ), among which at least certain blocks contain respectively at least one set of spectral parameters representing a linear prediction filter. Such a method of detection implements, for a current block among said at least certain blocks and for which at least a plurality of spectral parameters of said set have been previously decoded, the steps consisting in: - determining (S1), among said plurality of previously decoded spectral parameters, the index of the first spectral parameter closest to a threshold frequency, - calculating (S2) at least one criterion on the basis of said determined index, - deciding (S3) whether said predetermined frequency band is detected in said current block, as a function of the criterion calculated.
