Abstract (en)  
[origin: CN104441935A] The invention relates to a printing machine, comprising a first cylinder with a first gear, a second cylinder with a second gear, and an adjusting device making the second cylinder and the second gear being adjusted to a second cylinder position from a first cylinder position relative to the first cylinder and the first gear. In the first cylinder position, the first gear is meshed with the second gear. In the second cylinder position, the first gear and the second gear separate from meshing. The printing machine also comprises a finger protection device in a rod shape or a fusiform shape, a face-shaped protective component which can adjust supporting, and a transmission mechanism. The protective component is used to protect the first cylinder and/or prevent from being influenced by the first cylinder. The adjusting device is connected with the finger protection device through the transmission mechanism, so that when the second cylinder is adjusted to the second cylinder position from the first cylinder position, the finger protection device is forced to be adjusted from a first protection position to a second protection position. In the condition that the second cylinder is adjusted to the second cylinder position, the protective component is adjusted to between the first cylinder and the second cylinder.
