Abstract (en)
[origin: EP2687921A1] The method involves displaying first time information provided by a time base corresponding to an active mode of operation, and testing a first criterion associated with second time information. A second criterion relating to motion information provided by a detection unit of a port (10) of an electronic apparatus (100) is tested. A third criterion is represented to physical quantity such that a passage of the active mode is activated to a user. The position of a rotor of an electric motor is calculated at regular intervals when a needle is identical to generate least interference.
