Abstract (en)

[origin: WO2014121871A1] The invention relates to a method for analysing events that occur in a system, which consists of system components that communicate with one another internally by means of a common database and are connected to a system environment of the system by means of at least one first interface of the system, said method comprising the following steps: isolation (S1) of a system component of the system from the system environment if an integrity component of the system detects the occurrence of a certain event in the system component; transfer (S2) of the control of the isolated system component to an analysis component of the system by the integrity component, which analysis component establishes a communication connection to an external analysis unit by means of a second interface of the system; and analysis (S3) of the event that occurred in the isolated system component by the external analysis unit on the basis of the component data of the isolated system component that are stored in the common database of the system.
