Abstract (en)

[origin: WO2014207117A1] The invention relates to a device (10) for forming hollow cylindrical bodies (11). The device has a plurality of stations (12). A tool (13) is allocated to each station. The tools (13) are arranged on a common tool carrier (14). The tool carrier (14) can be moved between two reversing positions (UA, UB) via a main drive (15). Said reciprocating movement (H) is executed intermittently. One of the two reversing positions forms a rest position in which the tool carrier (14) stops in a rest phase (R). While the tool carrier (14) occupies the rest position (UA) in the rest phase (R), a transport device (23) transports the bodies (11) from one station (12) to the respective next station (12).
