Abstract (en)
A FBDDA amplifier (10) comprising: a first differential input stage (1a, 1b), which receives an input voltage (Vin); a second differential input stage (1c, 1d), which receives a common-mode voltage (V CM); a first resistive-degeneration group (12) coupled to the first differential input; a second resistive-degeneration group (16) coupled to the second differential input; a differential output stage, generating an output voltage; a first switch (14) coupled in parallel to the first resistive-degeneration group (12); and a second switch (18) coupled in parallel to the second resistive-degeneration group (16). The first and second switches (14, 18) are driven into the closed state when the voltage input (Vin) assumes a first value such that said first input stage operates in the linear region, and are driven into the open state when the voltage input (Vin) assumes a second value, higher than the first value, such that the first input stage operates in a non-linear region.
