Abstract (en)  
[origin: WO2015066514A2] A hockey stick includes a blade and a shaft meeting at an elbow region. A crown located along the top edge of the elbow region has an increased width, an increased height, or both, relative to crowns found in existing hockey blades. This enhanced crown helps to transfer load (or energy) from the shaft to the blade in the elbow region where such transfer is limited by existing designs. It does so without sacrificing puck handling and control, since the puck-contacting faces of the blade are not affected by the presence of the crown.
