Abstract (en)
[origin: WO2016162891A1] A cylinder lock (1) comprising a fixed stator (3) and a rotor (4), which is accommodated in a respective cavity (5) of the stator (3) and can rotate with respect to the stator (3). The rotor (4) comprises a substantially longitudinal space (6) for the functional accommodation of a respective key (2). Between the rotor (4) and the stator (3) there are respective accommodation channels for translating encoding elements: the channels are open onto the substantially longitudinal space (6). The substantially longitudinal space (6) comprises at least one protruding ridge (7) which is arranged substantially transversely with respect to the space (6) and divides the two far side portions of the space (6). In at least one section of the stator (3) and the rotor (4) there is at least one secondary conduit (8) for the slideable accommodation of at least one pin (9) the end tip (10) of which protrudes into one of the two far side portions of the space (6) and the base end of which is aligned with the discontinuity surface between stator (3) and rotor (4). The at least one pin (9) translates, during the insertion of the key (2) into the space (6), within the at least one secondary conduit (8) toward the stator (3), and the end tip (10) of the pin (9) is accommodated, when the key (2) is fully inserted in the space (6), in a respective recess (11) of the key (2) with consequent alignment of its base end with the discontinuity surface between stator (3) and rotor (4).
