Abstract (en)

[origin: WO2015144305A1] The invention creates a method in a processor for performing a cryptographic calculation. The performance of the calculation involves the application of a basic masking, by means of which intermediate values are used in the calculation as masked intermediate values. The performance of the calculation additionally involves the application of a folding and a secondary masking. The folding involves the calculation of the masked intermediate value using the unmasked intermediate value and at least one secondary intermediate value. The secondary masking involves the calculation, for each intermediate value masked by means of the basic masking, under random control, being performed either with the masked intermediate value or with the one's complement of the masked intermediate value.
