Abstract (en)
[origin: EP3197171A1] The present technology relates to a receiving apparatus and a receiving method that can minimize the effect of double laps of the time information indicating the order in which BB frames are selected in channel bonding. The receiving apparatus receives a plurality of divided streams that is a plurality of data slices to which BB frames of a BB stream that is a stream including the BB frames are distributed; selects a next BB frame from selectable BB frames on the basis of a bit information item indicating a remaining number of bits necessary to assemble a packet in which a BB header added to the BB frame is stored when the BB frame is stored in the packet; and reassembles the plurality of divided streams as the BB stream originally assembled by sequentially processing the BB frames in order in which the BB frames are selected. The present technology can be applied, for example, to channel bonding such as PLP bundling.
