Abstract (en)

[origin: EP3217721A1] The present invention discloses a network-side device, user equipment, and a blind area management method, so as to enable user equipment in a blind area in a high-frequency communications system to restore normal communication as quickly as possible. The network-side device includes a receiving module configured to receive measurement information sent by user equipment, a determining module configured to determine a status of the user equipment according to the measurement information, and a blind area state processing module. The blind area state processing module starts a quick beam search process when the user equipment is in a beam biased state, so as to find a new beam pair capable of converting the user equipment to a normal communication state; converts the status of the user equipment to a blocked state if no new beam pair capable of converting the user equipment to the normal communication state is found within a preset time; and when the status of the user equipment is the blocked state, instructs the user equipment to break a high-frequency connection, and enables the network-side device to perform data communication with the user equipment by using a low frequency band.
