Abstract (en)
[origin: WO2016181084A1] The invention relates to a method involving the following steps: using thermocompression to create, in a first mould (20), a screen (4) comprising two parts (7a, 7b) arranged relative to one another in a first configuration that allows them to be released from the mould, said parts each comprising a fibrous and porous thermal insulation layer (5) and a heat-reflecting metal sheet (6); placing said parts side by side in juxtaposition in a second mould the moulding cavity of which corresponds to the geometry of said panel that is to be obtained, so that said parts can, by being pressed firmly against the wall of said cavity, adopt a second configuration corresponding to said geometry, said fibrous layer facing toward the inside of said cavity; injecting into said cavity a mixture that is a precursor of foam, so as to form a core (2) overmoulding said fibrous layer; then, after the foam has expanded, releasing said panel obtained from the mould.
